1. EXECUTIVE SUMMARY

This document, Deliverable D2.1 “Reports of the workshops and results of sampling design optimization for selected case studies”, describes the activities performed and the results achieved under Task 2.1 “Sampling design optimization in all the metiers, including SSF, and identification of sampling hierarchy” of the STREAMLINE project.

One training workshop was organized online (Microsoft Teams) on 29th November – 1st December 2021, and was attended by 36 experts from nine EU Member States of the Mediterranean and Black Sea. The Workshop was chaired by Isabella Bitetto (COISPA, Italy), Task 2.1 Leader, in cooperation with Alessandro Ligas (CIBM, Italy), STREAMLINE Coordinator.

The workshop opened with a general overview of the main objectives of the STREAMLINE regional grant and the strict cooperation with the RCG Med&BS activities with the common target of achieving the expected results of coordinated regional work for the fisheries data collection in the Mediterranean and Black Seas. The training activity started from an overview of the sampling optimization tools with a description of the new features to be developed under STREAMLINE project. The main objective of this training was to allow the experts to familiarize with the tools utilizing a dummy dataset. After the presentation of each script, specific sessions were dedicated to the individual work on the codes; during these sessions clarifications were asked by the participants and the answers were given in plenary.

Taking into consideration the experience gained in the previous grants, and criteria such as the relevance of the stocks/fisheries, data availability and enforcement of multi-annual management plans, four case studies were identified and a reference group of experts were also identified for each case study.

In the following months, specific quality checks on the datasets to be utilized for the four case studies were carried out in preparation of the optimization analysis.

Then, a series of virtual meetings by case study were organized during the 2022 in order to support experts in carrying out the optimization and the simulation of alternative sampling design scenarios.

Preliminary results for each case study, including an idea of the possible change of sampling costs associated to alternative sampling designs, were presented during the RCG annual meeting in September 2022 and the feedback of the national correspondents were collected to be considered in the finalization of the analyses.

Finally, the results of the four case studies, summarized in this deliverable, were finalized and shared among the National Correspondents in order to be taken into consideration for the draft non-binding Regional Work Plans.

2. INTRODUCTION

Task 2.1 has been focusing on the sampling design optimization in the metiers relevant in the study areas, including SSF.

This task has been aimed at:

- The generalization of the SDTool and BioSimTool originally developed in the STREAM project (Ligas, 2019). In particular, an upgrade of the SDTool was carried out to allow to take into account a different number of positive trips for each species included in the case study. Moreover, additional quality indicators, focusing on the variability of the corresponding relevant estimates (e.g. von Bertalanffy parameters, size at first maturity, modes, anti-modes, amplitude ratio) have been included in BioSim Tool.
- Application of SDTool and BioSim Tool to the four selected case studies to provide a set simulations on alternative sampling design scenarios widely discussed with the experts of the study areas to support the drafting of the Regional Work Plans for the Mediterranean and Black Sea.

3. OUTCOMES OF THE TRAINING WORKSHOP

Under STREAMLINE Task 2.1, a training workshop on sampling design optimization R tools met online from the 29th November to the 1st December 2021, and was attended by 36 experts from nine EU Member States of the Mediterranean and Black Sea. The Workshop was chaired by Isabella Bitetto (COISPA, Italy), Task 2.1 Leader, in cooperation with Alessandro Ligas (CIBM, Italy), STREAMLINE Coordinator.

The training activity started with a presentation by Ms Bitetto providing an overview of the sampling optimization tools with a description of the new features foreseen under STREAMLINE project. The main objective of this training was to allow the experts to familiarize with the tools utilizing a dummy dataset. To facilitate the use of the scripts and avoid conflict problems due to the use of the *knitr* package, the SDTool scripts have been extracted from the .Rmd.

SD Tool was implemented for the first time within MARE/2014/19 Med&BS project and further improved within STREAM project (MARE/2016/22). This tool allows, through bootstrap technique, to resample the historical data studying the Coefficient of Variation (CV), the raised LFDs and the Earth Mover Distance (EMD) for different stratifications (spatial, temporal, and technical) in association with the number of primary sampling units (i.e. trips) for a set of species.

The SD Tool v.2 includes options allowing a flexible definition of the sampling scheme. The optimization can be carried out on:

- different technical stratifications, introducing options to define the technical strata on the basis of gear (level 4) and/or metier, grouping strata with similar characteristics;
- different temporal aggregations, in order to make flexible the stratification by quarter and/or semester, depending on fisheries and target species specifications;
- different spatial aggregations, grouping data of stocks considered shared among MSs in order to get results on the whole area of the stock (not only by GSA).

The statistical principle behind the SDTool is represented by the CV decreasing curve, when increasing the number of sampling units. This curve is, firstly, interpolated and, secondly, the part of the curve where the tangent changes and begins to flatten (i.e. the curvature range) is considered as a suitable trade-off between the precision and the sampling effort. Then, the sample size (in term of sampling units) corresponding to that part of the curve is proposed as “optimal” sample size.

BioSim Tool was implemented for the first time within STREAM project (MARE 2016/22), taking advantage of the work carried out by ICES WKBIOPIM. This tool allows, through bootstrap technique as well, to resample the historical data studying the Coefficient of Variation (CV) and the Earth Mover Distance (EMD) and to derive possible sub-samples to be applied on length measurements. Moreover, an optimal number of individuals to be sampled for sex, maturity and age (the latter stratified by length class) by species can be derived.

The new developments foreseen under STREAMLINE projects are mainly represented by the implementation of additional quality indicators to the ones developed and tested in STREAM taking into account the work carried out in the ICES WKBIOPIM3 and the work by Wischniewski et al. (2020).

The new indicators are:

- Admissible dissimilarity Value (ADV), as a measure of sampling reliability based on the comparison of the modes, anti-modes and amplitude of the LFDs under different sampling scenarios;
- Mean length-at-age, mean age-at-length, parameters of the von Bertalanffy growth model, maturity ogive parameters, root mean squared prediction error (RMSPE), mean squared prediction error (MSPE) and the mean average percentage error (MAPE), to evaluate the variability of the relevant estimates (e.g. von Bertalanffy parameters, size at first maturity) under different scenarios and to identify a satisfactory sub-sampling strategy.

The technical requirements are:

- R version 3.6.3, due to the use of COST packages;
- libraries: Fishpifct, COSTcore, COSTdbe, COSTeda and data.table.

A detailed presentation of each step needed to run the scripts implemented in **SDTool** was made:

1. *Data preparation*: transformation of the data from the RCG format to the COST objects (CS and CL, for the SDTool) and to the SDEF tables (CA, HH, HL, SL, TR, CL) (for BioSim Tool); this step is carried out through the two scripts: Conversion from RCG CS to CS cost object and Conversion from RCG CL to CL cost object.
2. *InvestigateData* script: it provides information on the temporal, spatial and technical coverage of the dataset.
3. *RunOptimizationBYspecies* script: it allows to find the optimal range in terms of number of trips for each defined stratum on the basis of the density kernel function.
4. *RunScenario* and *RunEvaluation* scripts: allow to simulate different sampling designs and to evaluate the impact on precision and on LFDs respect to the baseline.

Similarly, a detailed presentation of each script implemented in **BioSimTool** was made:

1. *Data preparation*: transformation of the CA and HH SDEF tables in the format required by BioSim in Rdata format.
2. *B_data_simulation_LENGTH* script: it allows to derive an optimal number of length measurements for each defined stratum without significantly losing in precision (e.g.CV);
3. *B2_calculate_subsample* script: allows to estimate a subsample factor to be used in the *RunScenarios*script of SDTool, to simulate scenarios involving the sub-sampling;
4. *C_data_simulation_MATURITY*: allows to derive an optimal number of maturity data to be collected without significantly losing in precision (e.g. ogive CV);
5. *D_data_simulation_SEX-RATIO*: allows to derive an optimal number of sex data to be collected without significantly losing in precision (e.g. sex ratio CV);
6. *E_data_simulation_AGE*: allows to derive an optimal number of age data per length class to be collected without significantly losing in precision (e.g. ALK CV).

After the presentation of each script, specific sessions were dedicated to the individual work on the codes; during these sessions clarifications were asked by the participants and the answers were given in plenary. Moreover, some results of the individual exercises (e. g. different sampling scenarios results) were shown by the participants to the whole group and the interpretation of them were discussed and clarified.

An overview of the a priori quality check script, developed in STREAM under WP6, to verify the consistency of the detailed data, was also provided by Ms IB. These quality checks should be carried out before starting to work on the case studies.

A plenary discussion took place on the identification of the case studies to be implemented under STREAMLINE and to be presented to the RCG Med&BS as possible regional work plans on commercial fisheries (including SSFs) in the Mediterranean and Black Seas.

Taking into consideration the experience gained in the previous grants, and criteria such as the relevance of the stocks/fisheries, data availability and enforcement of multi-annual management plans, the following case studies were identified:

| Case Study n. | GSAs | Countries | Stocks | Fisheries |
|---------------|-----------|--------------------------|---|-------------------------------------|
| 1 | 29 | Bulgaria, Romania | <i>Sprattus sprattus</i> , <i>Scophthalmus maximus</i> | PTM, GNS |
| 2 | 1-2-5-6-7 | Spain, France | <i>Aristeus antennatus</i> , <i>Merluccius merluccius</i> , <i>Parapenaeus longirostris</i> | OTB_DES, OTB_MDD, OTB_DWS, LLS, GNS |
| 3 | 17-18 | Croatia, Italy, Slovenia | <i>Merluccius merluccius</i> , <i>Mullus barbatus</i> , <i>Nephrops norvegicus</i> , <i>Parapenaeus longirostris</i> , <i>Solea solea</i> | OTB_DES, FPO, TBB, GNS, GTR, LLS |
| 4 | 17-18 | Croatia, Italy, Slovenia | <i>Engraulis encrasicolus</i> , <i>Sardina pilchardus</i> | PTM, PS |

This list was provided to the RCG Med&BS for their consideration and final approval.

4. RESULTS OF THE FOUR CASE STUDIES

The analyses for the four case studies were performed by national experts with the support of Task 2.1 leader, Isabella Bitetto. The work was done both offline and through the organization of online workshops and meetings in the period March-September 2022.

4.1 CASE STUDY 1

DATA AVAILABILITY AND EXPLORATION

In the Black Sea (GSA 29), the species *Sprattus sprattus* (SPR) and *Scophthalmus maximus* (TUR) are mainly exploited respectively by the OTM and GNS métiers. The dataset provided by Bulgaria and Romania included data for both stocks for the two métiers. In addition, the métier FPN_LPF, targeting *S. sprattus*, was present in Romania (Figure 4.1.1). Although not originally included in the case study, also this métier was considered.

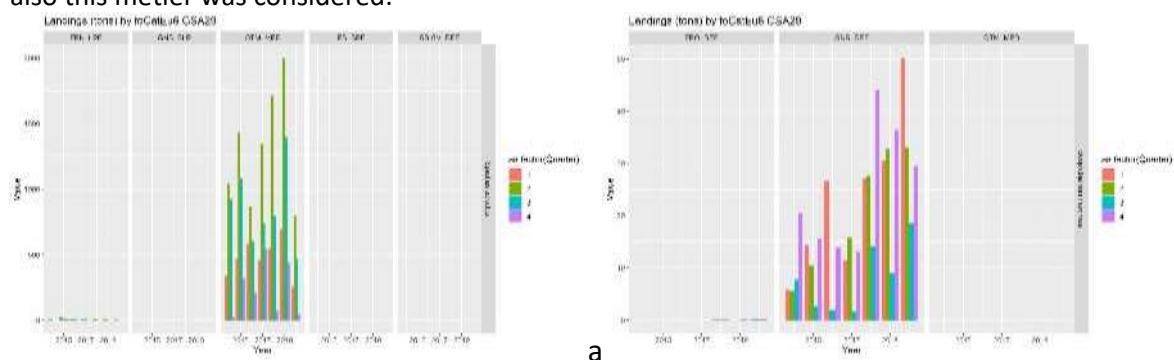

Figure 4.1.1 – *S. sprattus* (a) and *S. maximus* (b) in GSA 29. Landings by year, quarter and Fishing activity category European lvl 6.

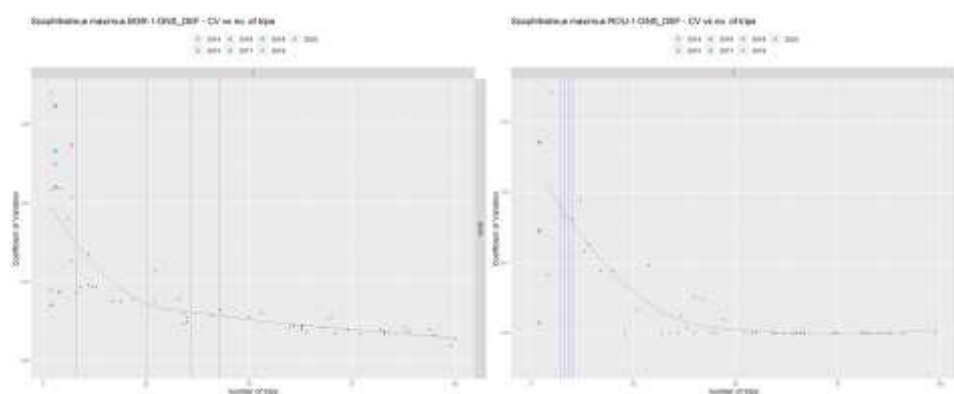

OPTIMIZATION RESULTS

The “optimal” sampling size was calculated through the 05_runOptimizationByspecies.Rmd script from the SD Tool. The analysis was based on the calculation of the CV associated to raised LFDs of a given species per year and per métier (Tab. 4.1.1). The CVs versus the number of trips are shown in Fig. 4.1.1, where vertical blue lines are referred to the first 4 local maxima of the density kernel function, used to derive the optimal sampling size range based on the historical sampling data and expert knowledge. Only the species characterizing the fishery were reported.

The results showed that *S. maxima* was every year under-sampled, whilst *S. sprattus* was in an optimal range or slightly under-sampled several years; in FPN_LPF, it was under-sampled every year.

Table 4.1.1 – Solutions (trips) of the optimization algorithm

| Species | Var1 | Var3 | solutions | maxCV | minCV | maxRR | minRR | meanRR | nolterations |
|---------|------|---------|-----------|-------|-------|-------|-------|--------|--------------|

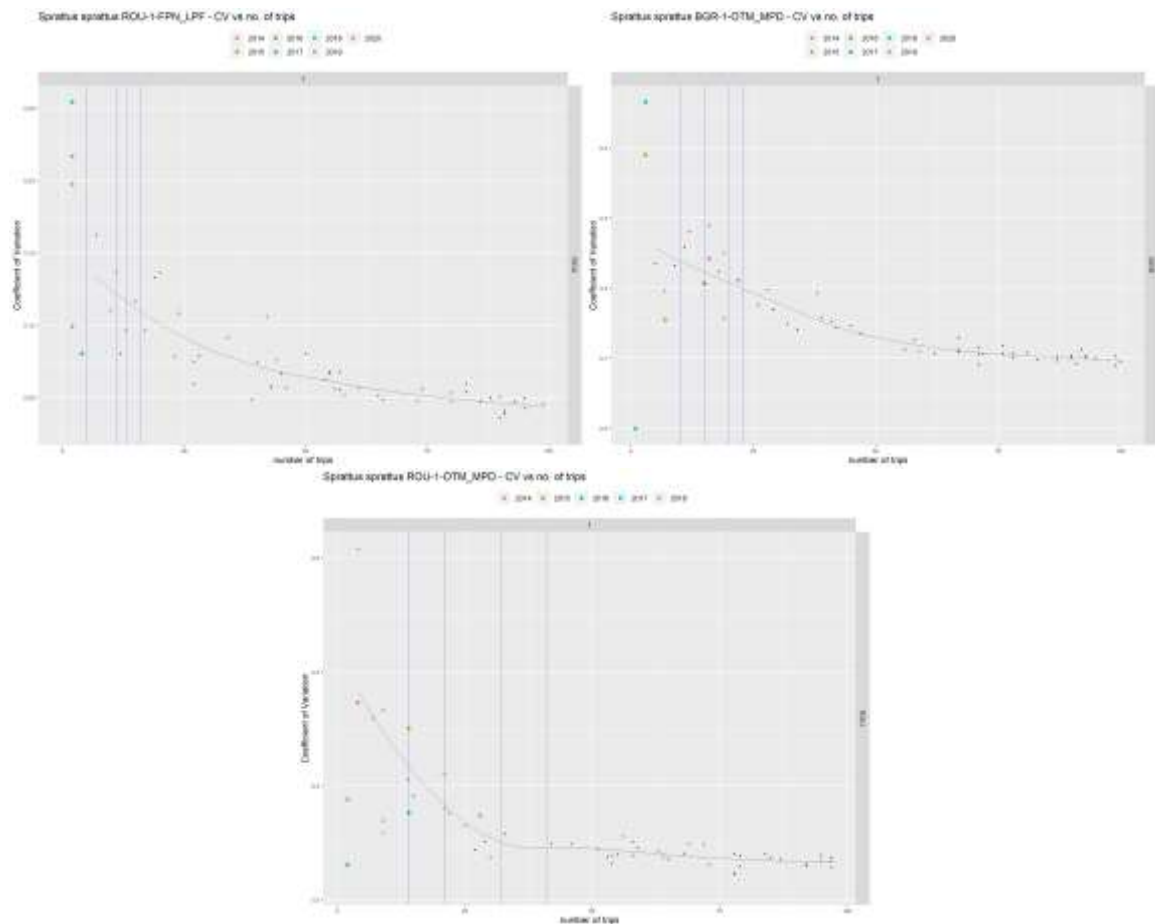

Figure 4.1.2 – CV versus number of trips for Case study 1. Vertical blue lines are referred to the optimal sampling size range inferred via the method.

SCENARIOS DESIGN

When analyzing the solutions derived from optimization results, the experts of the study area decided to explore the following scenarios, corresponding to an increase of the number of trips respect to the current Work Plan (indicated as Baseline; Tab. 4.1.2). Moreover, a scenario characterized by the decrease of the number of individuals against the increase of the number of trips (based on a subsample of ½ applied only to samples with more than 30 specimens) was explored.

Table 4.1.2 – Sampling design for the Case Study 1.

| Country | Métier | Scenario | n. of trips |
|---------|---------|--------------------------|-------------|
| BGR | GNS_DEF | Baseline | 8 |
| BGR | GNS_DEF | Scenario 1 | 12 |
| BGR | GNS_DEF | Scenario 2 | 20 |
| BGR | GNS_DEF | Scenario 2 + subsampling | 20 |
| BGR | OTM_MPD | Baseline | 10 |
| BGR | OTM_MPD | Scenario 1 | 12 |
| BGR | OTM_MPD | Scenario 2 | 16 |
| BGR | OTM_MPD | Scenario 2 + subsampling | 16 |
| ROU | FPN_LPF | Baseline | 11 |
| ROU | FPN_LPF | Scenario 1 | 13 |
| ROU | FPN_LPF | Scenario 2 | 15 |

| Country | Métier | Scenario | n. of trips |
|---------|---------|--------------------------|-------------|
| ROU | FPN_LPF | Scenario 2 + subsampling | 15 |
| ROU | GNS_DEF | Baseline | 8 |
| ROU | GNS_DEF | Scenario 1 | 9 |
| ROU | GNS_DEF | Scenario 2 | 10 |
| ROU | GNS_DEF | Scenario 2 + subsampling | 10 |
| ROU | OTM_MPD | Baseline | 14 |
| ROU | OTM_MPD | Scenario 1 | 16 |
| ROU | OTM_MPD | Scenario 2 | 20 |
| ROU | OTM_MPD | Scenario 2 + subsampling | 20 |

SCENARIOS RESULTS

The results on the Case Study 1 are reported in Table 4.1.3. The increase in the number of trips improved the CV in all cases. Specifically, for *S. maximus* and *S. sprattus* in Romania, the increase of the number of trips would be counter-balanced by the decrease of the number of specimens' measures. This could potentially impact the sampling costs.

Tab. 4.1.3 – Final results in terms of CV by species, country and métier.

| species | Country | Métier | scenario | CV | n. of trips | No indiv | % change trips | % change lengths |
|--------------------|---------|---------|---------------------|------|-------------|----------|----------------|------------------|

4.2 CASE STUDY 2

Streamlining the establishment of regional work plans in the Mediterranean and Black Sea

DATA AVAILABILITY AND EXPLORATION

Aristeus antennatus (ARA) in the Western Mediterranean Sea (GSAs 1, 2, 5, 6 and 7) is only exploited by the OTB métiers in the Spanish area; *Merluccius merluccius* (HKE) is exploited by the OTB métiers in both Spanish (GSAs 1, 2, 5, 6 and 7) and French area (GSA 7), by LLS in the Spanish area (GSAs 6 and 7) and by GNS in the Spanish area (GSA 6). *Mullus barbatus* (MUT) caught by OTB_DEF was also included in the analysis for the Spanish areas (GSAs 1, 5, 6 and 7) and for the French area. *Parapenaeus longirostris* (DPS) and *Nephrops norvegicus* (NEP) are exploited by the OTB_DEF in the Spanish area (GSAs 5, 6 and 7) (Figures 4.2.1 a-g).

Some data were considered not robust and were excluded from the analysis, in the Spanish area: *N. norvegicus* for OTB_DEF in the GSA 2, for OTB_DWS in the GSAs 1, 2, 5, 6 and 7, for OTB_MDD in the GSA 5; *P. longirostris* for OTB_DWS in the GSAs 5, 6 and 7, for OTB_MDD in the GSA 5; *M. merluccius* caught for OTB_DWS and OTB_MDD in the GSA 6. In the French area data excluded were: *M. merluccius* caught by GNS and LLS; *M. barbatus* caught by GNS; *N. norvegicus*, *A. antennatus* and *P. longirostris*.

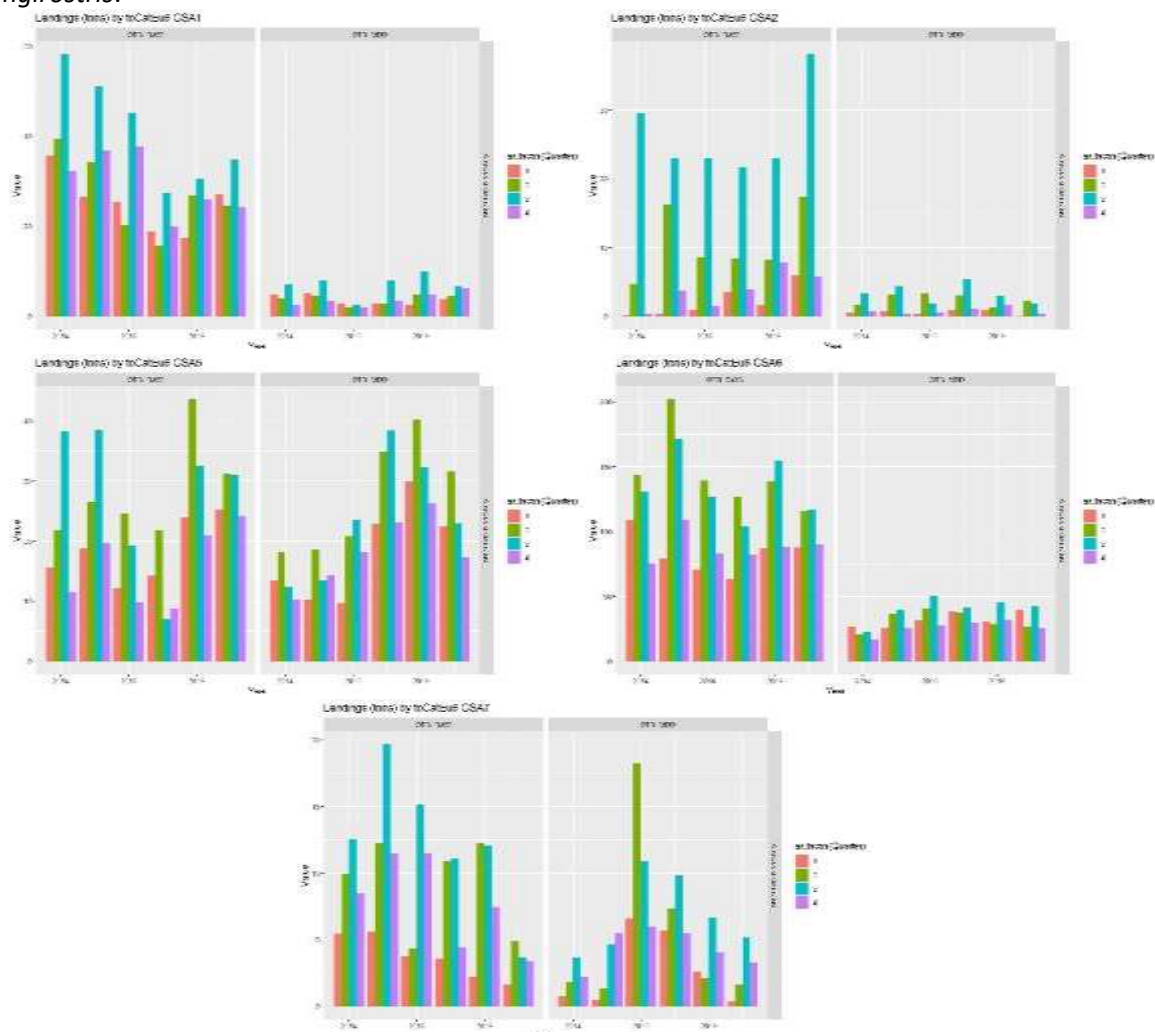

Figure 4.2.1 a – *A. antennatus* in GSAs 1, 2, 5, 6 and 7 (Spanish area). Landings by year, quarter and Fishing activity category European Ivl 6.

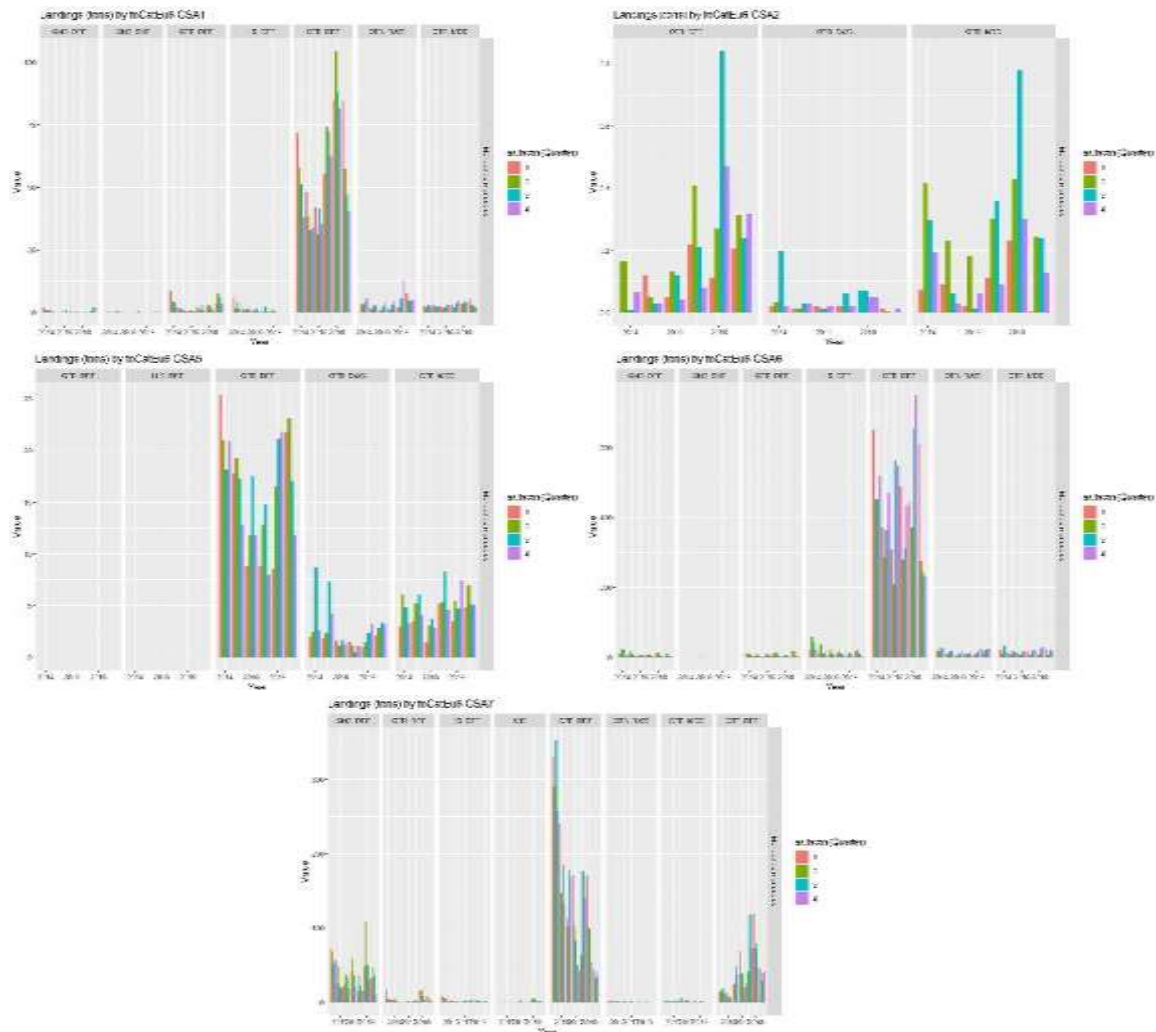

Figure 4.2.1 b – *M. merluccius* in GSAs 1, 2, 5, 6 and 7 (Spanish area). Landings by year, quarter and Fishing activity category European Ivl 6.

Figure 4.2.1 e – *N. norvegicus* in GSAs 1, 5, 6 and 7 (Spanish area). Landings by year, quarter and Fishing activity category European lvl 6.

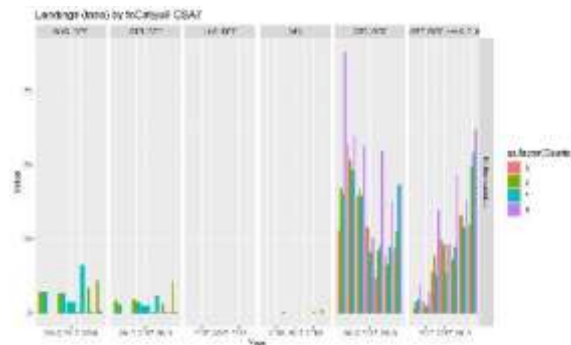

Figure 4.2.1 f – *M. barbatus* in GSA 7 (French area). Landings by year, quarter and Fishing activity category European Ivl 6.

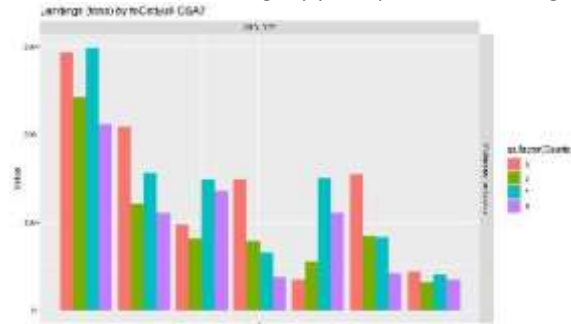

Figure 4.2.1 g – *M. merluccius* in GSA 7 (French area). Landings by year, quarter and Fishing activity category European Ivl 6.

OPTIMIZATION RESULTS

The “optimal” sampling size was calculated through the 05_runOptimizationBYspecies.Rmd script from the SD Tool. The analysis was based on the calculation of the CV associated to raised LFDs of a given species per year and per métier (Tab. 4.2.1 a-f). The CVs versus the number of trips are shown in Fig. 4.2.1 a-f, where vertical blue lines are referred to the first 4 local maxima of the density kernel function used to derive the optimal sampling size range based on the historical sampling data and expert knowledge. Only the species characterizing the fishery were reported. The results showed that in the Spanish GSAs:

- For GSA1 OTB_DEF, the current sampling is within the optimal range for the main target species (MUT and DPS);
- For GSA5 OTB_DEF, the current sampling is within the optimal range for the main target species (NEP);
- For GSA6 OTB_DEF, the current sampling is within the optimal range for the main target species (DPS);
- For GSA7 OTB_DEF, the current sampling corresponds to a slight under-sampling for the main target species (HKE, DPS and NEP);
- For GSA5 OTB_MDD, the current sampling corresponds to a slight under-sampling for NEP and ARA, whilst it is in the optimal range for HKE;
- For GSAs 1, 2, 5 and 6 OTB_DWS, the current sampling for ARA (the main target species) is in the optimal range, whilst it corresponds to a slight under-sampling for GSA 7;
- For GSAs 6 and 7 LLS_DEF, the current sampling for HKE (the main target species) is within the optimal range;
- For GSA 6 GNS_DEF, the current sampling for HKE (the main target species) is within the optimal range.

In the French part of the GSA7, the current sampling of OTB_DEF is in the optimal range and in some years highlights a slight over-sampling for the main target species (HKE and MUT).

Table 4.2.1 a – Solutions (trips) of the optimization algorithm GSA7 FRA.

| Species | Var1 | Var2 | Var3 | solutions | maxCV | minCV | maxRR | minRR | meanRR | noliterations |

SCENARIOS DESIGN

For each métier and GSA, the species characterizing the fishery were identified; on these species an occurrence factor was computed as the number of positive trips on the planned trips. The numbers of trips used in the scenarios were obtained multiplying the optimization solutions by the factor of the species characterizing the fishery. In detail, in the Spanish area:

- GSA1 OTB_DEF: the average between the 2nd and the 3rd solutions multiplied by the factor of DPS and MUT was used for the Scenario 1;
- GSA1 OTB_DEF: the 4th solutions multiplied by the factor of DPS and MUT was used for the Scenario 2;
- GSA5 OTB_DEF: the average between the 1st and the 2nd solutions multiplied by the factor of NEP was used for the Scenario 1;
- GSA5 OTB_DEF: the 2nd solutions multiplied by the factor of NEP was used for the Scenario 2;
- GSA6 OTB_DEF: the average between the 2nd and the 3rd solutions multiplied by the factor of DPS was used for the Scenario 1;
- GSA6 OTB_DEF: the 3rd solutions multiplied by the factor of DPS was used for the Scenario 2;
- GSA7 OTB_DEF: the average between the 1st and the 2nd solutions multiplied by the factor of DPS, HKE and NEP was used for the Scenario 1;
- GSA7 OTB_DEF: the 2nd solutions multiplied by the factor by the factor of DPS, HKE and NEP was used for the Scenario 2;
- GSA1 OTB_DWS: the 3rd solutions multiplied by the factor of ARA was used for the Scenario 2;
- GSA1 OTB_DWS: the average between the number of trips of Baseline and Scenario 2 was used for the Scenario 1;
- GSA2 OTB_DWS: the 1st of ARA solutions was used for the Scenario 1 (number of trips positive higher than the planned);
- GSA2 OTB_DWS: the 2nd solutions was used for the Scenario 2 of ARA (number of trips positive higher than the planned);
- GSA5 OTB_DWS: the 1st solution multiplied by the factor of ARA was used for the Scenario 1;
- GSA5 OTB_DWS: the 2nd solution multiplied by the factor of ARA was used for the Scenario 2;
- GSA6 OTB_DWS: the 1st solution multiplied by the factor of ARA was used for the Scenario 1;
- GSA6 OTB_DWS: the 2nd solution multiplied by the factor of ARA was used for the Scenario 2;
- GSA7 OTB_DWS: the 1st solution multiplied by the factor of ARA was used for the Scenario 1;
- GSA7 OTB_DWS: the 2nd solution multiplied by the factor of ARA was used for the Scenario 2;
- GSA5 OTB_MDD: the average of the 1st solutions multiplied by the factor of ARA, NEP and HKE was used for the Scenario 1;

- GSA5 OTB_MDD: the average of the 2nd solutions multiplied by the factor of ARA, NEP and HKE was used for the Scenario 1;
- GSA6 GNS_DEF: the average between the 2nd and the 3rd solutions multiplied by the factor of HKE was used for the Scenario 1;
- GSA6 GNS_DEF: the 3rd solutions multiplied by the factor of HKE was used for the Scenario 2;
- GSA6 LLS_DEF: the 1st solution multiplied by the factor of HKE was used for the Scenario 1;
- GSA6 LLS_DEF: the 2nd solution multiplied by the factor of HKE was used for the Scenario 2;
- GSA7 LLS_DEF: the average between the 2nd and the 3rd solutions multiplied by the factor of HKE was used for the Scenario 1;
- GSA7 LLS_DEF: the 3rd solutions multiplied by the factor of HKE was used for the Scenario 2.

In detail, in the French area:

- GSA7 OTB_DEF: the average between the 1st and the 2nd solutions of HKE and MUT was used for the Scenario 1;
- GSA7 OTB_DEF: the 3rd solutions of HKE and MUT was used for the Scenario 2.

Moreover, a scenario characterized by the decrease of the number of individuals against the increase of the number of trips (based on a subsample of ½ applied only to samples with more than 30 specimens) was explored.

The Table 4.2.2 shows the scenarios explored in the Case Study 2.

SCENARIOS RESULTS

In Tables 4.2.3 a-f, the results on the Case Study 2 are reported.

In GSA1 (Spain), for OTB_DEF mainly targeting *M. barbatus* and *P. longirostris*, the 50% reduction of the trips monitored would increase the CV of about 4-6%, highlighting that an important reduction of the trip monitoring costs would have a limited impact on the sampling precision of these stocks. For OTB_DWS, mainly characterized by *A. antennatus* landings, the 25% increase of the fishing trips do not reduce sensitively the CV.

For GSA2 (Spain), where OTB_DWS targets mainly *A. antennatus*, the decrease of about 11% of trips would maintain approximately the same sampling precision of the current sampling design. This could significantly impact the sampling costs.

In GSA5 (Spain), for OTB_DEF, mainly targeting *N. norvegicus*, the 33% reduction of the trips monitored would maintain the CV approximately at the same level of the current sampling, while decreasing of one third the costs associated to the trips monitoring. For OTB_DWS, the 100% increase of fishing trips would allow to have a slight improvement in sampling precision of *A. antennatus* (-4% CV); also for OTB_MDD, the 67% increase of fishing trips would allow to have a slight improvement in sampling precision (-4% on the CV) for *A. antennatus*.

In GSA6 (Spain), for GNS_DEF and LLS_DEF the increase in fishing trips would not allow to improve the sampling precision for *M. merluccius*; for OTB_DEF, mainly characterized by *P. longirostris* and *M. barbatus* landings, the 72% reduction would increase the CV of deep-water pink shrimp from 16 to 26%, while maintaining the CV around 20% for red mullet; for OTB_DWS, mainly targeting *A. antennatus*, the reduction of 64% of fishing trips and relevant costs, in combination to a 76% reduction in length measurements, would allow to have a CV below 20%, with an important reduction in sampling costs (e.g. trip and man-hours).

In GSA7 (Spain), for all the métier explored, the increase in fishing trips would allow to maintain or increase the current sampling precision on all the species at different extents.

In GSA7 (French), the reduction of the number of trips does not affect positively the CV. The results show that on one hand for hake scenario 3 would increase the CV by 5%, while reducing the costs associated to the sampled trips by 35%.

4.3 CASE STUDY 3

DATA AVAILABILITY AND EXPLORATION

The métier to be explored were OTB_DEF, FPO, TBB, GNS, GTR, LLS in the Adriatic Sea (GSAs 17 and 18). None of the selected species (*Merluccius merluccius*, *Mullus barbatus*, *Nephrops norvegicus*, *Parapenaeus longirostris*, *Solea solea*) is targeted by FPO, which was then excluded from the analysis. *M. merluccius* (HKE) is mainly caught by OTB and LLS (GSA18 only); *M. barbatus* (MUT) is mainly caught by OTB and nets (GNS and GTR, GSA18 only); *N. norvegicus* (NEP) and *P. longirostris* (DPS) are mainly caught by OTB; *S. solea* (SOL) is caught by nets and TBB (GSA17 only). The dataset we used included data from Italy and Croatia; Slovenian data were excluded (Figures 4.3.a-e).

OPTIMIZATION RESULTS

The “optimal” sampling size was calculated through the 05_runOptimizationBYspecies.Rmd script from the SD Tool. The analysis was based on the calculation of the CV associated to raised LFDs of a given species per year and per métier (Tab. 4.3.1). The CVs versus the number of trips are shown in Fig. 4.2.1 a-c, where vertical blue lines are referred to the first 4 local maxima of the density kernel function used to derive the optimal sampling size range based on the historical sampling data and expert knowledge. Only the species characterizing the fishery were reported. The figures showed that:

- In GSA18, the current sampling of OTB_DEF is optimal for the main target species (MUT, HKE and DPS);
- In GSA18, the current sampling of LLS_DEF is under-sampling the main target species (HKE);
- In GSA18, the current sampling of NETS (GNS+GTR) is under-sampling the main target species (MUT);
- In GSA17, the current sampling of OTB_DEF in Italy and in Croatia is optimal for the main target species (MUT, HKE and NEP);
- In GSA17, the current sampling GNS, GTR and TBB is optimal for the main target species (SOL).

SCENARIOS DESIGN

In this exercise, two sampling designs (Tab.4.3.2) have been compared with the current one (baseline) to explore the impact on precision, using the CV (of LFDs) on the target species (*M. merluccius*, *M. barbatus*, *P. longirostris*, *S. vulgaris*, *N. norvegicus*) of the métier listed in the previous paragraph,. For each Country, GSA and métier, the optimal number of trips has been estimated both by quarter and year. The trade-off among the species for each métier has been found on the basis of the species characterizing the fishery, using the following ratio: total number of planned trips/positive trips to the species. The species with ratio <2.5 were selected as characterizing the fishery.

Scenario 1 was defined following these criteria:

- For OTB_DEF, an average of the 1st solutions of the main species (optimization at quarter level) was considered for both GSA;
- For LLS (present only in GSA 18), the 1st solution (optimization at year level) on European hake was used;
- Considering NETS, the optimization was actually based on a unique species, occurring often in less than 40% of the trips; therefore, Scenario1 was carried out doubling (based on local experts knowledge) the number of trips provided by the first solution for red mullet;
- According to the same rationale, for GNS, GTR and TBB in GSA 17, the 1st solution for common sole was used, and Scenario 1 was defined with a 50% (based on local experts knowledge) increased number of trips respect to the 1st solution.

Scenario 2 is like Scenario 1 for all the Countries and métier, except GSA 17 Italian OTB_DEF and GNS:

- For OTB_DEF, an average of the 2nd solutions of the main species (optimization at year level) was considered;

- For GNS an average of the 1st and 2nd solutions of sole was considered.

For Scenario 2, sub-sampling by species and category, where possible, was applied (Tab. 4.3.3). The sub-sampling factors were estimated by means of the BioSim Tool 1.01 scripts.

In the simulations, the different number of positive trips for each species, Country and métier has been taken into account.

Tab. 4.3.2 – Scenarios applied in the Case Study 3

| Area | Métier (short code) | Baseline | Scenario_1 | Scenario_2 |
|-----------|---------------------|----------|------------|------------------------------------|
| GSA 18 | OTB_DEF | 52 | 69 | 69 + sub-sample by cat and species |

SCENARIOS RESULTS

The results on the Case Study 3 are reported in Table 4.3.3 .

In Croatia, the increase in fishing trips monitored does not show an important improvement in the precision (2-7%), and the reduction of the number of length measurements through sub-sample has the effect of worsening the precision for the 5 species monitored.

In the Western side of GSA17, the increase in fishing trips monitored does not show an important improvement in the precision (1-2%), and in some cases there is no improvement, and the reduction of the number of length measurements through sub-sample has the effect of worsening the precision for the 5 species monitored.

In GSA18, the increase in fishing trips monitored improves the CV, especially for longlines, and the reduction of the number of length measurements through sub-sampling scenarios highlighted the possibility of reducing or maintaining the man-hours while diversifying the sampling (monitoring more fishing trips).

Tab. 4.2.3 – Final results in terms of CV by species, country and métier.

4.4 CASE STUDY 4

DATA AVAILABILITY AND EXPLORATION

The small pelagic species *E. encrasicolus* (ANE) and *S. pilchardus* (PIL) in the Adriatic Sea (GSAs 17 and 18) are mainly exploited by the PS and PTM métiers. The dataset we used include data for Croatia and Italy, Slovenian data were excluded (Figures 4.4.1 a-b).

Figure 4.4.1 a – *E. encrasicolus* in GSAs 17 and 18. Landings by year, quarter and Fishing activity category European Ivl 6.Figure 4.4.1 b – *S. pilchardus* in GSAs 17 and 18. Landings by year, quarter and Fishing activity category European Ivl 6.

OPTIMIZATION RESULTS

The “optimal” sampling size was calculated through the 05_runOptimizationBYspecies.Rmd script from the SD Tool. The analysis was based on the calculation of the CV associated to raised LFDs of a given species per year and per métier (Tab. 4.4.1). The CVs versus the number of trips are shown in Fig. 4.4.2, where vertical blue lines are referred to the first 4 local maxima of the density kernel function used to derive the optimal sampling size range based on the historical sampling data and expert knowledge. Only the species characterizing the fishery were reported. The figures showed that the current monitoring has been under-sampling every year PIL caught by PS in Italy, whilst the current sampling of the other combination species/métier has been in the optimal range for several years.

Table 4.4.1 – Solutions (trips) of the optimization algorithm

SCENARIOS DESIGN

Streamlining the establishment of regional work plans in the Mediterranean and Black Sea

For Croatia, the scenarios were based on the optimal solutions on sardine (main target of the fishery), while for Italy on anchovy. Despite for Croatia and Italy PS_SPF the optimal number of trips was found in line with the current number of positive trips to sardine (Croatia) and anchovy (Italy), it was decided to explore an increase by about 50% of trips to evaluate the actual improvement in precision. For Italy PTM_SPF, the results of the optimization show a situation of oversampling for anchovy; for this reason the optimal number of trips was decreased by 30%, corresponding to the higher solution (Table 4.4.2). An additional scenario, requested by local experts, was included for PS_SPF in Croatia.

Tab. 4.4.2 – Scenarios applied in the Case Study 4

| Area | Country-métier | Baseline | Scenario 1 | Scenario 2 | Scenario 2 |
|-----------|----------------|----------|------------|-----------------------------|------------|
| GSA 17 | HRV-PS | 72 | 105 | 105 + sub-sample by species | 82 |
| GSA 17-18 | ITA PS | 28 | 39 | 39 + sub-sample by species | None |
| GSA 17-18 | ITA PTM | 46 | 30 | 46 + sub-sample by species | None |

For Scenario 2, sub-sampling by species was applied. The sub-sampling factors were estimated applying BioSim Tool (Tab.4.4.3).

In the simulations, the different number of positive trips for each species, Country and métier has been taken into account.

Tab. 4.4.3 – Sub-samplings by species and category from BioSim tool and applied in the Case Study 4

| Area | commCat | Métier_Gear | Sub_sample | SPECIE |
|---------------|---------|-------------|------------|--------|
| GSA17 HRV | ALL | PS | 0.25 | ANE |
| GSA 17-18 ITA | ALL | PS | 0.25 | ANE |
| GSA 17-18 ITA | ALL | PTM | 0.5 | ANE |
| GSA17 HRV | ALL | PS | 0.25 | PIL |
| GSA 17-18 ITA | ALL | PS | 1 | PIL |
| GSA 17-18 ITA | ALL | PTM | 0.5 | PIL |

SCENARIOS RESULTS

The results on the Case Study 4 are reported in Table 4.4.3.

For Croatia, it would be advisable to increase by 45% the number of fishing trips to reduce by a half the length measurements needed to achieve a CV equal or smaller than the CV corresponding to current sampling design. For Italy, the increase by 40% of the number of monitored trips for PS would allow to reduce the CV of anchovy by 3% only. For PTM, the decrease of monitored trips (35%) is not advisable. The results show that, while maintaining the same number of trips, it would be possible to reduce by a half the number of measurements.

Tab. 4.4.3 – Final results in terms of CV by species, country and métier.

| species | Var1 | Var3 | scenario | CV | no_trip | no_indiv | % change length | % change trips |

5 CONCLUSIONS

In this deliverable, the outcomes of the training workshop on sampling optimization tools held in November-December 2021 were presented. The workshop was organized to allow the experts of the different Member States to familiarize with the STREAM R tools on design optimization for biological sampling.

During the workshop four case studies were identified, because of relevance for Management Plans in Mediterranean and Black Sea. For each case study, reference experts were identified for running the analyses.

After the workshop a series of virtual meetings were organized by case study, providing technical and methodological support.

The application of SDTool and BioSim Tool to the Black Sea, Western Med (Spain and France) and Adriatic Sea allowed to provide a quantitative idea of how the sampling design could be optimized in each investigated fishery, in terms of number of trips to be monitored and length measurements.

Task 2.1 results allowed to evaluate the impact of alternative sampling designs on the precision of raised LFDs of relevant stocks and to derive the possible impact of the trip monitoring costs and man-hours costs associated to the sampling.

The results of the four case studies were described and discussed during the RCG Med&BS 2022 annual meeting (6-9 September 2022) in order to be used for the draft non-binding RWP submitted in October 2022. Feedback from the MS were collected and taken into account to refine the analyses.

The present results are expected to be complemented by an ad hoc evaluation of the sampling effort dedicated to the collection of biological information (e.g. maturity, age), requiring the purchase of samples and a dedicated laboratory work for samples processing. This part of the analysis was not carried out because the data provided presented, except in few specific cases, important gaps and/or high uncertainty on the individual data (e.g., age, sex, maturity). Nevertheless, the results achieved so far represent a robust basis for the further work that will be performed in the future by the incoming ISSG on Sampling Optimization (Scientific Network) to better refine the analyses and propose future sampling plans based on an optimized sampling strategy.

Task 2.1 Sampling design optimization in all the métiers, including SSF, and identification of sampling hierarchy

Report of the Online Workshop on sampling design optimization R tools

29th November – 1st December 2021, Microsoft Teams

The Workshop on sampling design optimization R tools organized under the Task 2.1 of the STREAMLINE project met online from the 29th November to the 1st December 2021 (Microsoft Teams platform; see Annex I – Agenda), and was attended by 36 experts from nine EU Member States of the Mediterranean and Black Sea (see Annex II – List of participants). The Workshop was chaired by Isabella Bitetto (COISPA, Italy), Task 2.1 Leader, in cooperation with Alessandro Ligas (CIBM, Italy), STREAMLINE Coordinator.

The workshop opened with a general overview of the main objectives of the STREAMLINE regional grant and the strict cooperation with the RCG Med&BS activities with the common target of achieving the expected results of coordinated regional work for the fisheries data collection in the Mediterranean and Black Seas.

Ms Charis Charilaou, who led the Work Package 7 under the previous STREAM regional grant (MARE/2016/22), provided a presentation on the outcomes of STREAM WP7 and the feedback from the experts who attended the training workshops organized under the STREAM project. This knowledge and experience were taken into account in updating the R scripts and tool, and organizing the present workshop.

The training activity started with a presentation by Ms Bitetto providing an overview of the sampling optimization tools with a description of the new features foreseen under STREAMLINE project. The main objective of this training was to allow the experts to familiarize with the tools utilizing a dummy dataset. The use of the dummy dataset was also suggested by STREAM WP7 and is aimed to focus on the methodological and technical aspects rather than the possible issues on the data. A set of other workshops and trainings will be organized in the next weeks to apply the tools on the identified case studies to run the sampling scenarios and to interpret the results. The results of the case studies analyses will be presented to the RCG for their consideration as possible draft regional work plans to be submitted by October 2022.

To facilitate the use of the scripts and avoid conflict problems due to the use of the *knitr* package, the SDTool scripts have been extracted from the .Rmd.

SD Tool was implemented for the first time within MARE/2014/19 Med&BS project and further improved within STREAM project (MARE/2016/22). This tool allows, through bootstrap technique, to resample the historical data studying the Coefficient of Variation (CV), the raised LFDs and the Earth Mover Distance (EMD) for different stratifications (spatial, temporal, and technical) in association with the number of primary sampling units (i.e. trips) for a set of species.

The SD Tool v.2 includes options allowing a flexible definition of the sampling scheme. The optimization can be carried out on:

- different technical stratifications, introducing options to define the technical strata on the basis of gear (level 4) and/or métier, grouping strata with similar characteristics;
- different temporal aggregations, in order to make flexible the stratification by quarter and/or semester, depending on fisheries and target species specifications;
- different spatial aggregations, grouping data of stocks considered shared among MSs in order to get results on the whole area of the stock (not only by GSA).

The statistical principle behind the SDTool is represented by the CV decreasing curve, when increasing the number of sampling units. This curve is, firstly, interpolated and, secondly, the part of the curve where the tangent changes and begins to flatten (i.e. the curvature range) is considered as a suitable trade-off between the precision and the sampling effort. Then, the sample size (in term of sampling units) corresponding to that part of the curve is proposed as “optimal” sample size.

BioSim Tool was implemented for the first time within STREAM project (MARE 2016/22), taking advantage of the work carried out by ICES WKBIOTIM. This tool allows, through bootstrap technique as well, to resample the historical data studying the Coefficient of Variation (CV) and the Earth Mover Distance (EMD) and to derive possible sub-samples to be applied on length measurements. Moreover, an optimal number of individuals to be sampled for sex, maturity and age (the latter stratified by length class) by species can be derived.

The new developments foreseen under STREAMLINE projects are mainly represented by the implementation of additional quality indicators to the ones developed and tested in STREAM taking into account the work carried out in the ICES WKBIOTIM3 and the work by Wischniewski et al. (2020). The new indicators are:

- Admissible dissimilarity Value (ADV), as a measure of sampling reliability based on the comparison of the modes, anti-modes and amplitude of the LFDs under different sampling scenarios;
- Mean length-at-age, mean age-at-length, parameters of the von Bertalanffy growth model, maturity ogive parameters, root mean squared prediction error (RMSPE), mean squared prediction error (MSPE) and the mean average percentage error (MAPE), to evaluate the variability of the relevant estimates (e.g. von Bertalanffy parameters, size at first maturity) under different scenarios and to identify a satisfactory sub-sampling strategy.

The technical requirements are:

- R version 3.6.3, due to the use of COST packages;
- libraries: Fishpifct, COSTcore, COSTdbe, COSTeda and data.table.

A detailed presentation of each step needed to run the scripts implemented in **SDTool** was made:

5. *Data preparation*: transformation of the data from the RCG format to the COST objects (CS and CL, for the SDTool) and to the SDEF tables (CA, HH, HL,SL, TR, CL) (for BioSim Tool); this step is carried out through the two scripts: Conversion from RCG CS to CS cost object and Conversion from RCG CL to CL cost object.
6. *InvestigateData* script: it provides information on the temporal, spatial and technical coverage of the dataset.
7. *RunOptimizationBYSpecies* script: it allows to find the optimal range in terms of number of trips for each defined stratum on the basis of the density kernel function.
8. *RunScenario* and *RunEvaluation* scripts: allow to simulate different sampling designs and to evaluate the impact on precision and on LFDs respect to the baseline.

Similarly, a detailed presentation of each script implemented in **BioSimTool** was made:

7. *Data preparation*: transformation of the CA and HH SDEF tables in the format required by BioSim in Rdata format.
8. *B_data_simulation_LENGTH* script: it allows to derive an optimal number of length measurements for each defined stratum without significantly losing in precision (e.g.CV);
9. *B2_calculate_subsample* script: allows to estimate a subsample factor to be used in the *RunScenarioscript* of SDTool, to simulate scenarios involving the sub-sampling;
10. *C_data_simulation_MATURITY*: allows to derive an optimal number of maturity data to be collected without significantly losing in precision (e.g. ogive CV);
11. *D_data_simulation_SEX-RATIO*: allows to derive an optimal number of sex data to be collected without significantly losing in precision (e.g. sex ratio CV);
12. *E_data_simulation_AGE*: allows to derive an optimal number of age data per length class to be collected without significantly losing in precision (e.g. ALK CV).

After the presentation of each script, specific sessions were dedicated to the individual work on the codes; during these sessions clarifications were asked by the participants and the answers were given in plenary. Moreover, some results of the individual exercises (e. g. different sampling scenarios results) were shown by the participants to the whole group and the interpretation of them were discussed and clarified.

An overview of the a priori quality check script, developed in STREAM under WP6, to verify the consistency of the detailed data, was also provided by Ms IB. These quality checks should be carried out before starting to work on the case studies.

Finally, an overview on the script developed under the task 3.4 of STREAM project to evaluate the impact on the sampling costs of alternative sampling designs was given by Ms IB.

For further details, the material of the training workshop was made available the first day of the workshop on the sharepoint of the STREAMLINE Teams Group

(<https://streamline2021project.sharepoint.com/sites/STREAMLINETask2.1/Shared%20Documents/Fo rms/AllItems.aspx?RootFolder=%2Fsites%2FSTREAMLINETask2%2E1%2FShared%20Documents%2FG eneral&FolderCTID=0x01200018D5646BE891864089458B3BCC98D181>), subdivided in scripts, presentations, packages and background documents.

Presentations on the main outcomes and problems encountered of the five case studies implemented under the STREAM project were made by the experts who coordinated those case studies. The presentations served to feed the plenary discussion on the identification of the case studies to be implemented under STREAMLINE and to be presented to the RCG Med&BS as possible regional work plans on commercial fisheries (including SSFs) in the Mediterranean and Black Seas. Taking into consideration the experience gained in the previous grant, and criteria such as the relevance of the stocks/fisheries, data availability and enforcement of multi-annual management plans, the following case studies were identified:

| Case Study n. | GSAs | Countries | Stocks | Fisheries |
|---------------|-----------|--------------------------|--|-------------------------------------|
| 1 | 29 | Bulgaria, Romania | Sprattus sprattus, Scophthalmus maximus | PTM, GNS |
| 2 | 1-2-5-6-7 | Spain, France | Aristeus antennatus, Merluccius merluccius, Parapenaeus longirostris | OTB_DES, OTB_MDD, OTB_DWS, LLS, GNS |
| 3 | 17-18 | Croatia, Italy, Slovenia | Merluccius merluccius, Mullus barbatus, Nephrops norvegicus, Parapenaeus longirostris, Solea solea | OTB_DES, FPO, TBB, GNS, GTR, LLS |
| 4* | 17-18 | Croatia, Italy, Slovenia | Engraulis encrasicolus, Sardina pilchardus | PTM, PS |

*This case study was added after the consultation with the RCG Med&BS and the NCs.

This list was provided to the RCG Med&BS for the consideration and feedback before the implementation and analysis will be started.

A tentative list of case study leaders/teams was also drafted. An invitation to join the case study team was extended to all the participants. In addition, a roadmap was also drafted to organize the next steps towards the implementation of the case studies (data checks, analysis, identification and run of scenarios, estimation of costs, etc.) and their presentation to the RCG Med&BS by June 2022, at the very latest. This will allow the process of considering the submission of draft regional work plans on commercial fisheries.

The workshop closed at 13.00 CET on Wednesday 1st December 2021.

Annex I - Agenda

Monday 29th November, 09.00-16.30 CET

- 9.15-9.30, Connection to the online meeting
- 9.30, Welcome and opening of the works – A. Ligas (STREAMLINE Coordinator)
- 9.45, Presentation of the STREAMLINE project – A. Ligas
- 10.15, Summary of STREAM WP7 outputs – C. Charilaou
- 10.45, Coffee break
- 11.00, Overview of the sampling optimization tools with new features – I. Bitetto (Task 2.1 Leader)
- 13.00-14.30, Lunch break
- 14.30, Familiarization with the optimization tools using a dummy dataset – I. Bitetto
- 16.30, Closing of the works.

Tuesday 30th November, 09.00-16.30 CET

- 9.30, Familiarization with the optimization tools using a dummy dataset – I. Bitetto
- 11.00, Coffee break
- 11.15, Running of the optimization tools, solving technical problems, discussion on methodological aspects
- 13.00-14.30, Lunch break
- 14.30, BioSim Tool– I. Bitetto
- 15.30, Familiarization with the BioSim tool using a dummy dataset
- 16.30, Closing of the works.

Wednesday 01st December, 09.00-13.00 CET

- 9.30, A priori quality checks on RCG CS format and costs evaluation– I. Bitetto
- 10.35, Coffee break
- 10.50, Summary of the case studies presented in STREAM, highlight on drawbacks and future developments in STREAMLINE – Persons in charge of STREAM case studies (10 minutes each)
- 11.45, Plenary discussion on possible case studies for future regional work plans
- 12.45, Wrap-up and drafting of the roadmap of the activities under Task 2.1
- 13.00, Closing of the works.

Annex II - List of participants

| Name and surname | Affiliation | Member State |
|---------------------|-------------|--------------|
| Aina De Mesa | IEO | Spain |
| Alberto Santojanni | CNR-IRBIM | Italy |
| Alessandro Ligas | CIBM | Italy |
| Cristian Danilov | NIMRD | Romania |
| Charis Charilaou | DFMR | Cyprus |
| Claudia Musumeci | CIBM | Italy |
| Danilo Scannella | CNR-IRBIM | Italy |
| Elitsa Petrova | IFR | Bulgaria |
| Encarnacions Garcia | IEO | Spain |
| Fabio Falsone | CNR-IRBIM | Italy |

| | | |
|--------------------|-----------|----------|
| Farrugia Hazel | MAFA-DFA | Malta |
| Feriha Tserkova | IFR | Bulgaria |
| Francesco Masnadi | CNR-IRBIM | Italy |
| Gema Martínez | IEO | Spain |
| George Tiganov | NIMRD | Romania |
| Gregoire Certain | IFREMER | France |
| Grigoraș Daniel | NIMRD | Romania |
| Ioannis Thasitis | DFMR | Cyprus |
| Isabella Bitetto | COISPA | Italy |
| Ivelina Zlateva | IO-BAS | Bulgaria |
| Kostas Touloumis | FRI | Greece |
| Lazaros Tsiridis | FRI | Greece |
| Livia Menziani | MIPAAF | Italy |
| Loredana Casciaro | COISPA | Italy |
| Madalina Galatchi | NIMRD | Romania |
| Martina Scanu | CNR-IRBIM | Italy |
| Matteo Chiarini | CNR-IRBIM | Italy |
| Miguel Vivas | IEO | Spain |
| Norbert Billet | IFREMER | France |
| Orfanidis Georgios | FRI | Greece |
| Paola Pesci | UNICA | Italy |
| Paun Catalin | NIMRD | Romania |
| Violin Raykov | IO-BAS | Bulgaria |
| Stefanos Kavadas | HCMR | Greece |
| Vanja Čikeš Keč | IOF | Croatia |
| Vita Gancitano | CNR-IRBIM | Italy |
